Lec 21: Roots of Nonlinear Equations

The Rootfinding Problem

Problem Statement

Rootfinding Problem

Given a continuous scalar function of a scalar variable, find a real number r such that f(r)=0.

- r is a **root** of the function f.
- The formulation f(x)=0 is general enough; e.g., to solve g(x)=h(x), set f=g-h and find a root of f.

Iterative Methods

- Unlike the earlier linear problems, the root cannot be produced in a finite number of operations.
- Rather, a sequence of approximations that formally converge to the root is pursued.

Iteration Strategy for Rootfinding. To find the root of f:

- **1** Start with an initial iterate, say x_0 .
- **2** Generate a sequence of iterates x_1, x_2, \ldots using an iteration algorithm of the form

$$x_{k+1} = g(x_k), \quad k = 0, 1, \dots$$

3 Continue the iteration process until you find an x_i such that $f(x_i)=0$. (In practice, continue until some member of the sequence seems to be "good enough".)

MATLAB's FZERO

fzero is MATLAB's general purpose rootfinding tool.

Syntax:

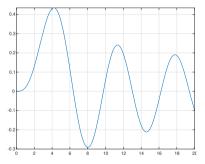

```
x_zero = fzero( <function>, <initial iterate> )
x_zero = fzero( <function>, <initial interval> )
[x_zero, fx_zero] = ....
```

Example

The roots of J_m , a Bessel function of the first kind, is found by

- Plot the function.
- Find approximate locations of roots.

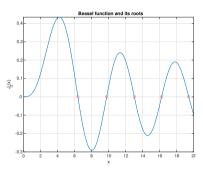

```
J3 = @(x) besselj(3,x);
fplot(J3,[0 20])
grid on
guess = [6,10,13,16,19];
```

Example (cont')

• Then use fzero to locate the roots:

```
omega = zeros(size(guess));
for j = 1:length(guess)
  omega(j) = fzero(J3, guess(j));
end
hold on
plot(omega, J3(omega), 'ro')
```

Conditioning

Sensitivity of the rootfinding problem can be measured in terms of the (magnification) condition number:

$$(\underline{absolute} \ condition \ number) = \frac{|\underline{abs.} \ error \ in \ output|}{|abs. \ error \ in \ input|},$$

where, in the context of finding roots of f,

output: r (root)

$$(f \mapsto f + \epsilon g)$$

• error/change in output: Δr

$$(r \mapsto r + \Delta r)$$

Conditioning (cont')

• The perturbed equation

$$f(r) + f'(r)\Delta \Gamma + \frac{f'(r)}{2}(\Delta \Gamma) + \cdots + \frac{f(r+\Delta r)}{2} + \epsilon g(r+\Delta r) = 0$$
(Since $r + \Delta r$ is a roof is linearized to (Taylor expansion)
$$g(r) + g'(r)\Delta r + g''(r)\Delta r + g''(r)\epsilon \Delta r \approx 0,$$

ignoring $O((\Delta r)^2)$ terms¹.

• Since f(r) = 0, we solve for Δr to get

$$\Delta r \approx -\epsilon \frac{g(r)}{f'(r) + \epsilon g'(r)} \approx -\epsilon \frac{g(r)}{f'(r)},$$

for small ϵ compared with f'(r).

(alos. cond. number)
$$= \left| \frac{\Delta \Gamma}{\epsilon g} \right| \approx \frac{1}{|f'(r)|}$$

¹That is, terms involving $(\Delta r)^2$ and higher powers of Δr

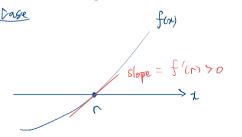

Conditioning (cont')

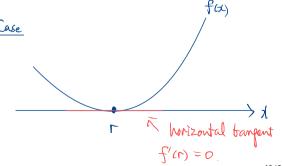

• Therefore, the absolute condition number of the rootfinding problem is

rootifinding problem
$$=\frac{1}{|f'(r)|},$$

which implies that the problem is highly sensitive whenever $f'(r) \approx 0$.

• In other words, if |f'| is small at the root, a computed *root estimate* may involve large errors.

Residual and Backward Error

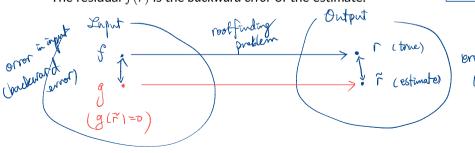

Exact problem Approx
$$f(r) = 0$$
 $f(\hat{r}) \approx 0$

- Recall (LLS) Solving
- Without knowing the exact root, we cannot compute the error.
- But the **residual** of a root estimate \tilde{r} can be computed:

(residual) =
$$f(\tilde{r})$$
.

- Small residual might be associated with a small error.
- The residual $f(\tilde{r})$ is the *backward error* of the estimate.

Means finding the 2-norm of residual b-Ax.

error in output (forward error)

Why? Define
$$g(x) = f(x) - f(\tilde{r})$$
.

Observe that \tilde{r} is a root of g because $g(\tilde{r}) = f(\tilde{r}) - f(\tilde{r}) = 0$.

Therefore, the backward error $f(x) - g(x) = f(x) - (f(x) - f(\tilde{r}))$
 $= f(\tilde{r}) = (residual)$

$$f(\tilde{r}) - f(\tilde{r}) = 0$$
,

packward error

 $= f(x) - (f(x) - f(\tilde{r}))$
 $= f(\tilde{r}) = (residual)$

of \tilde{r}

Multiple Roots

Definition 1 (Multiplicity of Roots)

Assume that r is a root of the differentiable function f. Then if

$$0 = f(r) = f'(r) = \dots = f^{(m-1)}(r)$$
 but $f^{(m)}(r) \neq 0$,

we say that f has a root of **multiplicity** m at r.

- We say that f has a **multiple root** at r if the multiplicity is greater than 1.
- A root is called **simple** if its multiplicity is 1.
- If r is a multiple root, the condition number is infinite.
- Even if r is a simple root, we expect difficulty in numerical computation if $f'(r) \approx 0$.
